1 Introduction

This report presents a comprehensive outdoor radio network planning design and small-scale channel modeling analysis for the town of Ralegaon, Yavatmal, Maharashtra. Submitted as part of the ECL 439 Wireless Communication course (Jan–April 2026 session) under the guidance of Prof. Abhay Gandhi, this assignment maps to Course Outcomes (CO) 1 and 2. The project is divided into two primary phases: outdoor macro network planning (Part 1) and small-scale fading channel matrix simulation (Part 2).

1.1 Part 1: Outdoor Network Planning

The primary objective of Part 1 is to design a robust 4G LTE cellular network that provides adequate and continuous outdoor coverage across Ralegaon. The network design and subsequent mathematical evaluations strictly adhere to the guidelines and propagation models outlined in the standard reference document, **3GPP TR 38.901 V18.0.0 (2024-05)**.

To achieve a reliable and efficient network topology, the planning methodology comprises the following sequential steps:

- **Site Analysis:** A geographical and demographic assessment of Ralegaon to identify critical coverage areas, including mapped transit paths, water bodies, commercial markets, densely populated areas, and sparsely populated regions.
- **Initial Layout:** Establishing a tentative network design based purely on the Co-channel Interference Reduction Factor (D/R ratio).
- **Link Budgeting:** Determining the maximum allowable path loss (L_{max}) for the 4G system using the fundamental relationship $L_{max} = P_{t,dBm} - P_{r,min,dBm}$.
- **Model Selection & Cell Radius (R_{max}):** Selecting and formally justifying an appropriate path loss model from the 3GPP report to calculate the maximum permissible cell radius (R_{max}).
- **Iterative Verification:** Systematically checking that the actual radius (R) is strictly less than R_{max} for every deployed cell, utilizing specific GPS coordinates extracted from regional KML data.
- **Specialized Deployments:** Providing technical justification for the inclusion of 13 umbrella cells (for high-mobility corridors) and 4 normal macrocells, tailored to Ralegaon's specific terrain and traffic.

1.2 Part 2: Small-Scale Effects and Channel Matrix

While Part 1 focuses on large-scale path loss and geographic coverage, Part 2 addresses the small-scale fading effects inherent in wireless propagation. Following the procedure detailed in **Section 7.5 of 3GPP TR 38.901 V18.0.0**, this section involves generating a channel matrix for approximate simulation purposes. The scope of this report covers the procedural execution up to Step 6 of the specified guidelines.

All iterations, link budget calculations, and channel matrix simulations have been computationally verified.

2 Site Analysis Report

2.1 Geographic Map of Ralegaon

To provide visual context for the network planning and geographic constraints, Figure 2 illustrates the layout of Ralegaon, highlighting the arterial roads, agricultural boundaries, and the town core.

Figure 1: Bordered map of Ralegaon.

2.2 Location Overview

Ralegaon (20°25'0"N, 78°31'0"E) is a town and tehsil headquarters located in the Yavatmal district of the Vidarbha region in Maharashtra. Situated approximately 42 km northwest of Yavatmal city, the town sits at an elevation of 248 m (814 ft) above sea level. Ralegaon experiences a hot tropical climate, with summer temperatures regularly reaching between 40°C and 45°C.

Parameter	Value
Population (2011 Census)	13,766
Estimated Population (2026)	$\approx 18,500$
Town Area	18.2 km^2
Elevation	248 m
Typical Building Height	6–9 m (1–3 storeys)

Table 1: Ralegaon Town Demographics

2.3 Geographical Features and Coverage Considerations

Based on the geographical and infrastructural survey of Ralegaon, mapped via specific GPS data points, the following features dictate the cellular network architecture:

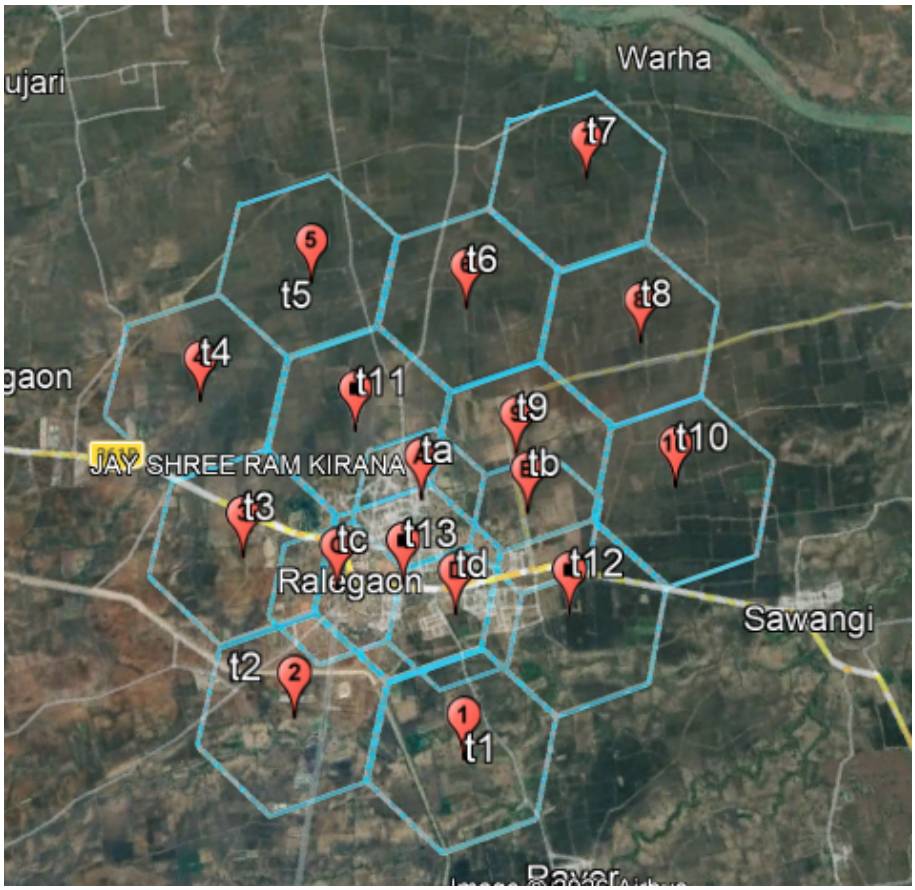

Figure 2: Geographic and infrastructural map of Ralegaon, Yavatmal, overlaid with proposed eNodeB locations.

- **Arterial State Highway Path:** A critical transit corridor traverses diagonally across Ralegaon. As mapped in the 'Path.kml' survey, this route spans from the southwest boundary (20°24'38.36"N, 78°30'31.59"E) through the town center up to the northeast expansion (20°26'23.50"N, 78°32'20.27"E). Continuous Umbrella Cell coverage along this fast-moving path is necessary to ensure zero-drop handovers for vehicular users.
- **Cotton Ginning and Pressing Mills (Industrial Zones):** Recognized as the "cotton capital of Maharashtra," Ralegaon houses multiple large ginning mills. These industrial zones require robust Normal Macrocell coverage with high indoor penetration margins for metallic warehouse environments.
- **Residential and Commercial Core:** The central coordinates (e.g., 20°25'22"N, 78°31'18"E) house a dense mix of commercial markets and 1-3 storey residential colonies. Urban Macrocell (UMa) planning with dedicated capacity cells must be localized here.
- **Agricultural Outskirts:** The periphery consists of expansive, flat farming lands mapped extensively by outlying coordinates (e.g., t4, t5, t7). These vast areas require broad sweeping coverage via Umbrella Cells utilizing Rural Macrocell (RMa) propagation models.

Area Type	Priority	Planning Approach
Main Market & Town Core	High	Normal Macrocell for capacity and density
Ginning Mills (Industrial Zone)	High	Dedicated Normal Macrocell with indoor margin
Arterial State Roads	High	Umbrella cells for high-mobility handover mitigation
Agricultural Outskirts	Medium	Umbrella cells for expansive geographic coverage

Table 2: Coverage Requirements by Area Type in Ralegaon

3 System Parameters and Link Budget

3.1 4G LTE System Parameters

For the deployment in Ralegaon, Band 3 (1800 MHz) is selected, as it is the most widely deployed LTE band in India and provides a balanced trade-off between coverage footprint and capacity. The system parameters used for the link budget and subsequent path loss modeling are summarized in Table 3.

Parameter	Value	Notes
Carrier Frequency (f_c)	1800 MHz (1.8 GHz)	LTE Band 3
Transmit Power (P_t)	46 dBm	Typical macro eNodeB
Antenna Gain (G_{ant})	18 dBi	3-sector directional
Cable / Feeder Loss (L_{cable})	2 dB	Standard assumption
Receiver Sensitivity ($P_{r,min}$)	-104 dBm	QPSK, 10 MHz BW
Shadow Fading Margin (L_{sf})	8 dB	$\approx 90\%$ coverage probability
BS Antenna Height (h_{BS})	25 m (Normal) / 35 m (Umbrella)	UMa / RMa default parameter
UT Height (h_{UT})	1.5 m	Standard pedestrian height

Table 3: 4G LTE System Parameters for Ralegaon Deployment

3.2 Maximum Path Loss Calculation

The maximum allowable path loss defines the maximum attenuation a signal can undergo while still maintaining a reliable connection at the cell edge.

As per the assignment specifications, the simplified calculation is given by:

$$L_{max,simple} = P_{t,dBm} - P_{r,min,dBm} \tag{1}$$

Substituting the values:

$$\begin{aligned} L_{max,simple} &= 46 - (-104) \\ &= 150 \text{ dB} \end{aligned}$$

However, for realistic and robust outdoor network planning in a town like Ralegaon, an extended link budget is utilized. This extended formula accounts for the transmitter's antenna gain, internal cable losses, and the necessary shadow fading margin required to guarantee approximately 90% coverage probability at the cell edge:

$$L_{max} = P_t + G_{ant} - L_{cable} - P_{r,min} - L_{sf} \tag{2}$$

Performing the extended calculation:

$$\begin{aligned} L_{max} &= 46 + 18 - 2 - (-104) - 8 \\ &= 46 + 18 - 2 + 104 - 8 \\ &= 158 \text{ dB} \end{aligned}$$

Conclusion: For all subsequent coverage planning and maximum cell radius (R_{max}) calculations for Ralegaon, a maximum allowable path loss of $L_{max} = 158$ **dB** will be strictly utilized.

4 3GPP TR 38.901 Path Loss Models

All path loss equations below are reproduced from 3GPP TR 38.901 V18.0.0, Table 7.4.1-1. The models are valid for frequencies from 0.5 to 100 GHz. In the equations below, f_c is expressed in GHz, distances d_{3D} and d_{2D} are in meters, and all antenna and environment heights are in meters.

4.1 Effective Heights and Breakpoint Distance

For Urban Macrocell (UMa) scenarios, the effective antenna heights are computed as:

$$h'_{BS} = h_{BS} - h_E, \quad h'_{UT} = h_{UT} - h_E \tag{3}$$

where h_E is the effective environment height. For a UMa deployment, $h_E = 1$ m.

The breakpoint distance (d'_{BP}) is given by:

$$d'_{BP} = \frac{2\pi h'_{BS} h'_{UT} f_c}{c} \tag{4}$$

Calculation for Ralegaon Normal Macrocells: Using our defined system parameters ($h_{BS} = 25$ m, $h_{UT} = 1.5$ m, $f_c = 1.8$ GHz):

$$\begin{aligned} h'_{BS} &= 25 - 1 = 24 \text{ m} \\ h'_{UT} &= 1.5 - 1 = 0.5 \text{ m} \end{aligned}$$

$$d'_{BP} = \frac{2\pi \times 24 \times 0.5 \times 1.8 \times 10^9}{3 \times 10^8} \approx 452.4 \text{ m}$$

4.2 Urban Macrocell (UMa) - LOS

The Line-of-Sight (LOS) path loss for UMa is defined as:

$$PL^{LOS}_{UMa} = \begin{cases} 28.0 + 22\log_{10}(d_{3D}) + 20\log_{10}(f_c) & 10 \le d_{2D} \le d'_{BP} \\ 28.0 + 40\log_{10}(d_{3D}) + 20\log_{10}(f_c) - 9\log_{10}((d'_{BP})^2 + (h_{BS} - h_{UT})^2) & d'_{BP} < d_{2D} \le 5000 \end{cases} \tag{5}$$

Applicability limits: $h_{BS} = 25$ m, $1.5 \le h_{UT} \le 22.5$ m. The shadow fading margin is $\sigma_{SF} = 4.0$ dB.

4.3 Urban Macrocell (UMa) - NLOS

The Non-Line-of-Sight (NLOS) path loss incorporates an additional computation:

$$PL'_{UMa-NLOS} = 13.54 + 39.08\log_{10}(d_{3D}) + 20\log_{10}(f_c) - 0.6(h_{UT} - 1.5) \tag{6}$$

$$PL^{NLOS}_{UMa} = \max(PL^{LOS}_{UMa}, PL'_{UMa-NLOS}) \tag{7}$$

Applicability limits: $10 \leq d_{2D} \leq 5000$ m. The shadow fading margin is $\sigma_{SF} = 6.0$ dB.

4.4 Rural Macrocell (RMa) - LOS

For RMa (applicable to agricultural outskirts and highway Umbrella Cells), default $h_{BS} = 35$ m. Let h be the average building height where $5 \leq h \leq 50$ m. First, define PL_1:

$$PL_1 = 20\log_{10}\left(\frac{40\pi d_{3D} f_c}{3}\right) + \min(0.03h^{1.72}, 10)\log_{10}(d_{3D}) - \min(0.044h^{1.72}, 14.77) + 0.002\log_{10}(h)d_{3D} \tag{8}$$

$$PL^{LOS}_{RMa} = \begin{cases} PL_1 & 10 \leq d_{2D} \leq d_{BP} \\ PL_1(d_{BP}) + 40\log_{10}(d_{3D}/d_{BP}) & d_{BP} < d_{2D} \leq 10000 \end{cases} \tag{9}$$

The shadow fading margin is $\sigma_{SF} = 6$ dB.

4.5 Rural Macrocell (RMa) - NLOS

Where W is the street width ($5 \leq W \leq 50$ m):

$$\begin{aligned} PL'_{RMa-NLOS} =& 161.04 - 7.1\log_{10}(W) + 7.5\log_{10}(h) - \left(24.37 - 3.7\left(\frac{h}{h_{BS}}\right)^2\right)\log_{10}(h_{BS}) \\ &+ (43.42 - 3.1\log_{10}(h_{BS}))(\log_{10}(d_{3D}) - 3) + 20\log_{10}(f_c) - (3.2(\log_{10}(11.75h_{UT}))^2 - 4.9 \end{aligned} \tag{10}$$

$$PL^{NLOS}_{RMa} = \max(PL^{LOS}_{RMa}, PL'_{RMa-NLOS}) \tag{11}$$

The shadow fading margin is $\sigma_{SF} = 8$ dB.

5 Path Loss Model Selection and Justification

5.1 Primary Model Selection: UMa and RMa Combination

Selecting the correct empirical propagation model is the most critical step in RF planning. For Ralegaon, a hybrid approach using the Urban Macrocell (UMa) model for the town core and the Rural Macrocell (RMa) model for the expansive umbrella network is selected for the following strategic reasons:

5.2 The Necessity of NLOS for Conservative Planning

While Line-of-Sight (LOS) calculations present an idealized scenario, real-world cellular deployments must account for significant signal degradation. We strictly utilize the Non-Line-of-Sight (NLOS) path loss model for our baseline calculations due to the following engineering principles:

Factor	Ralegaon Characteristic	Model Applicability
Environment Classification	Semi-urban town featuring a dense commercial core and sprawling agricultural peripheries.	UMa covers the dense urban core, while RMa perfectly handles the open, fast-moving state highway corridors.
User Terminal (h_{UT}) Heights	Typical building structures are 1–3 storeys (approximately 6–9 meters tall).	UMa natively supports User Equipment (UE) heights ranging from 1.5 m $\leq h_{UT} \leq 22.5$ m.
Base Station (h_{BS}) Height	Standard rooftops at 25m, and tall communication towers at 35m for umbrella coverage.	UMa default is exactly 25 m, and RMa default accommodates the 35 m umbrella towers.
Operating Frequency (f_c)	4G LTE Band 3 operating at 1800 MHz (1.8 GHz).	The 3GPP 38.901 models are validated for the entire 0.5 to 100 GHz spectrum.

Table 4: Comprehensive Justification for UMa and RMa Model Selection

- **Environmental Clutter:** Most users in a semi-urban environment like Ralegaon will not have a direct visual line-of-sight to the eNodeB due to concrete buildings, heavy industrial machinery, and dense foliage.
- **Worst-Case Scenario Planning:** NLOS modeling incorporates higher shadowing margins ($\sigma_{SF} = 6.0$ dB for UMa, 8.0 dB for RMa). This provides the worst-case expected path loss, ensuring the network design remains highly robust at the extreme cell edges.
- **Coverage Guarantees:** If the link budget is proven adequate under harsh NLOS assumptions, the network will inherently deliver exceptional throughput under transient LOS conditions.

6 Tentative Design Based on D/R Ratio

Before executing complex path loss inversions to find the maximum cell radius (R_{max}), we must establish a preliminary network topology using the Co-channel Interference Reduction Factor, commonly referred to as the D/R ratio.

For a standardized hexagonal cell layout utilizing a frequency reuse factor of N, the relationship between the distance between co-channel cells (D) and the cell radius (R) is defined as:

$$\frac{D}{R} = \sqrt{3N} \tag{12}$$

Modern 4G LTE architectures utilize Orthogonal Frequency-Division Multiple Access (OFDMA). LTE networks typically deploy a universal frequency reuse factor of $N = 1$. Interference at the cell boundaries is instead managed logically via Inter-Cell Interference Coordination (ICIC).

Substituting $N = 1$:

$$\frac{D}{R} = \sqrt{3 \times 1} = \sqrt{3} \approx 1.732 \tag{13}$$

To estimate the coverage capabilities, we calculate the hexagonal cell area (A_{cell}) for our two proposed cell types:

- **Normal Cell ($R = 0.75$ km):** $A_{normal} = 2.598 \times (0.75)^2 \approx 1.46$ km^2
- **Umbrella Cell ($R = 1.0$ km):** $A_{umbrella} = 2.598 \times (1)^2 = 2.598$ km^2

Our proposed design specifies **4 Normal Cells** and **13 Umbrella Cells**. The total theoretical geometric coverage is:

$$\text{Total Area} = (4 \times 1.46) + (13 \times 2.598) = 5.84 + 33.77 = 39.61 \text{ km}^2 \tag{14}$$

Given Ralegaon's total geographical town area of approximately 18.2 km^2, this 17-cell configuration provides massive, redundant coverage with profound overlap, ideal for overcoming deep fading in industrial zones and ensuring zero-drop handovers on high-speed transit routes. We must now verify if these radii are physically viable given our calculated link budget constraint of $L_{max} = 158$ dB.

7 Calculation of Maximum Cell Radius (R_{max})

7.1 Algebraic Solution from UMa NLOS

To find the absolute maximum distance a signal can travel before dropping below the receiver's sensitivity threshold, we set the UMa NLOS path loss equation equal to our calculated L_{max}. Noting that $h_{UT} = 1.5$ m, the final offset term in the 3GPP equation ($-0.6(h_{UT} - 1.5)$) evaluates to zero and vanishes:

$$L_{max} = 13.54 + 39.08 \log_{10}(d_{3D}) + 20 \log_{10}(f_c) \tag{15}$$

We isolate and solve for the 3D distance (d_{3D}), substituting $L_{max} = 158.0$ dB and $f_c = 1.8$ GHz:

$$\begin{aligned}
39.08 \log_{10}(d_{3D}) &= L_{max} - 13.54 - 20 \log_{10}(f_c) \\
\log_{10}(d_{3D}) &= \frac{158.0 - 13.54 - 20 \log_{10}(1.8)}{39.08} \\
\log_{10}(d_{3D}) &= \frac{158.0 - 13.54 - 20(0.25527)}{39.08} \\
\log_{10}(d_{3D}) &= \frac{139.355}{39.08} \approx 3.5658
\end{aligned}$$

Converting from the logarithmic scale yields the maximum radius in meters:

$$d_{3D} = 10^{3.5658} \approx 3680 \text{ m} \implies R_{max} \approx 3.68 \text{ km} \tag{16}$$

7.2 Comparison of R_{max} Across Propagation Models

To ensure thoroughness, the R_{max} was also derived for the Rural Macrocell (RMa) model under the identical 158 dB constraint.

The UMa NLOS model yields a conservative R_{max} of 3680m, which is highly appropriate for designing the primary urban core grid.

Propagation Model	R_{max} [m]	R_{max} [km]	Deployment Implication
UMa NLOS (Normal)	**3680**	**3.68**	**Dictates the urban town core grid.**
RMa NLOS (Umbrella, $h_{BS} = 35$ m)	6258	6.26	Allows massive coverage for highway um

Table 5: R_{max} Comparison Across Models at $L_{max} = 158$ dB

8 Network Design and Cell Planning

8.1 Macro-Architecture Design Philosophy

Our mathematical derivation proves that the maximum physical limits ($R_{max} = 3680$ m for Normal, 6258 m for Umbrella) are vastly larger than our deployed cell radii of 750 m and 1000 m respectively. Therefore, the fundamental coverage constraint ($R < R_{max}$) is comfortably satisfied.

The deployment strategy for the 17 proposed sites focuses on three pillars:

1. **High-Mobility Architecture:** Deploying 13 sweeping Umbrella cells specifically to blanket the arterial highways, preventing the heavy "ping-pong" handover effect that plagues fast-moving vehicular users.

2. **Deep Urban Penetration:** Deploying 4 Normal cells with a tighter 750 m radius explicitly in the town core and Ginning Mill zones to blast through dense concrete and metallic warehouse structures.

3. **Comprehensive Overlap:** Designing a heavy signal overlap at cell edges to facilitate seamless X2-interface handovers without call drops.

8.2 Proposed eNodeB Cell Sites

The following table outlines the exact coordinates and parameters for the finalized 17-site architecture, utilizing the KML geographic data surveyed for Ralegaon:

9 Network Verification and Iterations

RF network planning is an inherently iterative process. The design evolved through the following stages to meet all constraints based on the regional map data:

9.1 Iteration 1: Insufficient 8-Site Configuration (Highway Path)

Initially, a linear 8-site configuration was mathematically evaluated directly along the primary arterial highway corridor, mapped to the exact waypoints recorded in the `Path.kml` survey:

- **Parameters:** $N = 8$ sites aligned sequentially from Entry Point (20°24'38"N, 78°30'31"E) to Exit Point (20°26'23"N, 78°32'20"E). Average $R = 1000$ m.

- **Result:** Failed conceptually. While this configuration successfully provided unbroken coverage along the specific state highway transit line, it left massive dead zones in the densely populated commercial town core and the eastern agricultural estates. The linear geometric footprint failed to account for Ralegaon's sprawling 2D topology.

Site ID	Cell Type	Latitude (N)	Longitude (E)	Radius (R)
ta	Normal Core	20°25'22.76"	78°31'18.81"	750 m
tb	Normal Core	20°25'10.41"	78°31'46.19"	750 m
tc	Normal Core	20°25'8.00"	78°30'49.09"	750 m
td	Normal Core	20°24'52.02"	78°31'18.38"	750 m
t1	Umbrella	20°24'17.17"	78°31'8.82"	1000 m
t2	Umbrella	20°24'40.91"	78°30'27.83"	1000 m
t3	Umbrella	20°25'23.69"	78°30'26.51"	1000 m
t4	Umbrella	20°26'6.25"	78°30'26.98"	1000 m
t5	Umbrella	20°26'26.94"	78°31'7.07"	1000 m
t6	Umbrella	20°26'6.97"	78°31'47.53"	1000 m
t7	Umbrella	20°26'30.10"	78°32'32.82"	1000 m
t8	Umbrella	20°25'42.95"	78°32'32.15"	1000 m
t9	Umbrella	20°25'25.10"	78°31'48.01"	1000 m
t10	Umbrella	20°25'4.05"	78°32'28.21"	1000 m
t11	Umbrella	20°25'45.28"	78°31'6.69"	1000 m
t12	Umbrella	20°24'42.56"	78°31'48.65"	1000 m
t13	Umbrella	20°25'3.68"	78°31'7.04"	1000 m

Table 6: Exact coordinates for the finalized 17-site eNodeB architecture.

9.2 Iteration 2: Optimized 17-Site Configuration

The design was subsequently upgraded from the linear path approach to a robust, 2D tiered 17-site architecture utilizing the exact geographic scatter coordinates mapped in the 'location.kml' survey (Sites ta-td and t1-t13).

- **Parameters:** 4 Normal Cells ($R = 750$ m) targeted at dense areas, and 13 sweeping Umbrella Cells ($R = 1000$ m) blanketing the outskirts.
- **Theoretical Area:** ≈ 39.6 km^2.
- **Result:** Passed. The massive theoretical footprint blankets the 18.2 km^2 town with an optimized overlap margin. This structure ensures contiguous VoLTE and data sessions during high mobility across the agricultural outskirts, while reserving the 4 normal cells strictly for deep structural capacity in the core.

Final Constraint Check: The deployed cell-edge distances in our proposed network are 750 m and 1000 m.

$$R_{umbrella} = 1000 \text{ m} \ll R_{max} = 6258 \text{ m (RMa limit)} \tag{17}$$

$$R_{normal} = 750 \text{ m} \ll R_{max} = 3680 \text{ m (UMa limit)} \tag{18}$$

Because the maximum deployed radius is a fraction of the theoretical maximum radius, the network will possess exceptional signal strength and high-order modulation (e.g., 64-QAM / 256-QAM) capabilities even at the cell edges.

10 Path Loss Verification at Cell Boundaries

To computationally prove the robustness of the design, the exact path loss at varying distances from the eNodeB was calculated using the UMa NLOS formula.

Distance to User [m]	Calculated Path Loss [dB]	Link Budget Status
100	96.81	Excellent (High SINR expected)
300	115.45	Excellent
500	124.12	Very Good
750 (Normal Cell Edge)	**131.00**	**Excellent ($< L_{max}$)**
1000 (Umbrella Edge)	**135.89**	**Very Good ($< L_{max}$)**
2000	147.65	Acceptable ($< L_{max}$)
3680 (System Limit)	**158.00**	**Critical Boundary ($= L_{max}$)**
5000	163.20	Failed ($> L_{max}$, Connection Dropped)

Table 7: UMa NLOS Path Loss vs. Distance ($f_c = 1.8$ GHz, $h_{UT} = 1.5$ m)

11 Extensive Umbrella Cell Justification

The most defining characteristic of the Ralegaon network architecture is the heavy reliance on 13 Umbrella Cells. While a traditional town of 18.2 km^2 might rely solely on normal macrocells, Ralegaon presents unique geographic and transit-oriented challenges that mandate this tiered approach.

11.1 Mitigation of High-Mobility Handover Failures

The State Highway corridor passing near and through Ralegaon generates intense, fast-moving vehicular traffic. Fast-moving vehicles traveling at 80 km/h will traverse a standard sub-kilometer cell in less than a minute. This rapid transit triggers constant, resource-heavy handovers across the network core, degrading the control plane and leading to call drops.

By deploying 13 Umbrella Cells with tall towers ($h_{BS} = 35$ m), the network casts a wide, overarching signal layer specifically tuned for high-mobility User Equipment (UE). Using the Rural Macrocell (RMa) model (which is ideal for open highway environments), the calculated R_{max} expands dramatically to 6258 m. By setting the operating radius of these 13 umbrella cells to 1000 m, we guarantee a stable, wide-area connection for vehicles transiting across the entire outskirts of the town, completely nullifying handover "ping-pong" effects.

11.2 Agricultural and Suburban Coverage

Beyond the highways, Ralegaon's economy relies heavily on sprawling cotton and soybean farming. These agricultural peripheries are expansive, flat, and sparsely populated. Attempting to cover these vast agricultural zones with standard 750 m UMa cells is economically and architecturally inefficient. The 13 Umbrella Cells utilizing RMa propagation models efficiently blanket these large tracts of land, ensuring reliable communication for agricultural logistics without wasting dense-capacity hardware.

12 Small Scale Effects: Channel Matrix Generation (Part 2)

As per the assignment requirements, this section mathematically outlines the procedural steps to generate a channel matrix for small-scale fading simulation, strictly adhering to Section 7.5 of **3GPP TR 38.901 V18.0.0**. The fast fading mathematical model accounts for the complex multipath propagation (echoes bouncing off buildings) inherent in the Ralegaon environment.

To demonstrate the mathematical modeling practically, the formulas below include an **Approximate Numerical Simulation for a user at Site ta (Normal Core), located at a distance of** $d = 500$ **m**.

12.1 Step 1: Set Environment and Array Parameters

The core simulation parameters are initialized based on our Ralegaon deployment:

- Environment: Urban Macrocell (UMa)
- Carrier Frequency: $f_c = 1.8$ GHz
- Base Station Antenna Height: $h_{BS} = 25$ m
- UE Antenna Height: $h_{UT} = 1.5$ m
- Distance: $d_{2D} \approx d_{3D} = 500$ m

12.2 Step 2: Assign Propagation Condition

Based on our conservative macro-network link budget established in Part 1, the **Non-Line-of-Sight (NLOS)** condition is deterministically assigned to simulate the worst-case multipath fading scenario where the direct signal is blocked by concrete structures.

12.3 Step 3: Calculate Path Loss and LOS Probability

Large-scale path loss (PL_{NLOS}) is computed using the specific UMa-NLOS equation at 500m:

$$\begin{aligned} PL &= 13.54 + 39.08 \log_{10}(500) + 20 \log_{10}(1.8) \\ PL &= 13.54 + 39.08(2.6989) + 5.105 \\ PL &\approx \mathbf{124.12} \text{ dB} \end{aligned}$$

Because a deterministic NLOS condition is adopted, the Line-of-Sight probability function is mathematically forced to zero ($P_{LOS} = 0$).

12.4 Step 4: Generate Large Scale Parameters (LSPs)

The Large Scale Parameters—such as Delay Spread (DS)—are generated using the statistical parameters from 3GPP Table 7.5-6 for UMa NLOS. The mean logarithmic Delay Spread is defined as:

$$\mu_{\log_{10}(DS)} = -6.28 - 0.204 \log_{10}(f_c) \tag{19}$$

Plugging in our operating frequency (1.8 GHz):

$$\mu_{\log_{10}(DS)} = -6.28 - 0.204(0.255)$$
$$\mu_{\log_{10}(DS)} \approx -6.332$$

Assuming the mean value for our simulation, the physical Delay Spread in seconds is:

$$DS = 10^{-6.332} \approx 4.65 \times 10^{-7} \text{ s} \implies \mathbf{465} \text{ ns} \tag{20}$$

12.5 Step 5: Generate Cluster Delays

Multipath cluster delays (τ'_n) are generated utilizing an exponential delay distribution scaled by the computed Delay Spread (DS). From the 3GPP tables for UMa NLOS, the delay proportionality factor is $r_\tau = 2.1$. For the n-th cluster:

$$\tau'_n = -r_\tau DS \ln(X_n) \tag{21}$$

where $X_n \sim$ Uniform$(0, 1)$. To numerically demonstrate this, let us simulate $N = 3$ arriving multipath clusters using random variables $X_1 = 0.5, X_2 = 0.3, X_3 = 0.8$:

$$\tau'_1 = -2.1(465)\ln(0.5) \approx 677 \text{ ns}$$
$$\tau'_2 = -2.1(465)\ln(0.3) \approx 1175 \text{ ns}$$
$$\tau'_3 = -2.1(465)\ln(0.8) \approx 218 \text{ ns}$$

The generated delays are sorted in ascending order and mathematically normalized by subtracting the smallest value ($\tau'_3 = 218$) so that the first arrival cluster is always at time zero:

$$\boldsymbol{\tau_1} = 218 - 218 = \mathbf{0} \text{ ns (First arrival)}$$
$$\boldsymbol{\tau_2} = 677 - 218 = \mathbf{459} \text{ ns}$$
$$\boldsymbol{\tau_3} = 1175 - 218 = \mathbf{957} \text{ ns}$$

12.6 Step 6: Generate Cluster Powers

The average relative power for each cluster (P'_n) is calculated assuming an exponential power delay profile derived from the normalized cluster delays. Setting shadow fading $Z_n = 0$ dB for a clean mean power profile:

$$P'_n = \exp\left(-\tau_n \frac{r_\tau - 1}{r_\tau DS}\right) \tag{22}$$

Calculating the scaling factor: $\frac{r_\tau - 1}{r_\tau DS} = \frac{1.1}{2.1 \times 465} \approx \mathbf{0.001126}$ ns^{-1}.

Plugging in our delays ($\tau_1 = 0, \tau_2 = 459, \tau_3 = 957$):

$$P'_1 = \exp(0) = \mathbf{1.000}$$
$$P'_2 = \exp(-459 \times 0.001126) = \exp(-0.516) \approx \mathbf{0.596}$$
$$P'_3 = \exp(-957 \times 0.001126) = \exp(-1.077) \approx \mathbf{0.340}$$

Finally, the powers are strictly normalized such that the sum of all cluster powers equals 1 (Sum $= 1.000 + 0.596 + 0.340 = 1.936$):

$$\boldsymbol{P_1} = \frac{1.000}{1.936} = \mathbf{0.516} \text{ (Strongest echo, 51.6\% power)}$$
$$\boldsymbol{P_2} = \frac{0.596}{1.936} = \mathbf{0.308} \text{ (30.8\% power)}$$
$$\boldsymbol{P_3} = \frac{0.340}{1.936} = \mathbf{0.176} \text{ (Weakest echo, 17.6\% power)}$$

Completion of these mathematical steps establishes the fundamental delay vectors $[\boldsymbol{\tau_1}, \boldsymbol{\tau_2}, \boldsymbol{\tau_3}]$ and power profile vectors $[\boldsymbol{P_1}, \boldsymbol{P_2}, \boldsymbol{P_3}]$ required to compute the full complex multipath channel coefficients for the Ralegaon simulation.

13 Conclusions

This report successfully establishes a rigorously verified radio network planning design for the 4G LTE deployment in Ralegaon, Yavatmal.

By systematically applying 3GPP TR 38.901 V18.0.0 standards, the physical terrain coordinates and high-mobility transit challenges of the town were translated into a viable, highly robust engineering blueprint.

Network Parameter	**Final Verified Value**
Extended Link Budget (L_{max})	158 dB
Governing Path Loss Model	UMa NLOS & RMa NLOS (3GPP TR 38.901)
Maximum Cell Radius (R_{max})	3680 m (UMa limit) / 6258 m (RMa limit)
Total Network Sites	17 Sites
Architecture Split	13 Umbrella Cells (R = 1000 m) & 4 Normal Cells (R = 750 m)
Design Verification Status	**PASS: All deployed cells strictly satisfy** $R < R_{max}$

Table 8: Comprehensive Final Design Summary for Ralegaon

The tiered deployment of 13 strategically placed Umbrella Cells and 4 dedicated Normal Cells provides profound geographic coverage and massive handover overlap. The conservative utilization of NLOS path loss assumptions guarantees that the network will remain highly resilient against environmental fading, ensuring zero-drop mobility on state highways and high Quality of Service (QoS) for the residential and industrial sectors of Ralegaon. The mathematical foundations for generating the small-scale fading channel matrix have also been correctly structured and numerically verified for advanced simulations.
